Aikido vs TxPipe: Strike Finance Audit Comparison

Date: February 25, 2026 **Aikido Version**: 0.3.0 (75 detectors, multi-lane architecture) **Auditor**: TxPipe Shop (professional manual + automated audit)

Disclaimer / Methodology Note

> *This comparison report was prepared by the Aikido team as supplementary analysis. The manual classification of true positives, false positives, and false negatives is additional expert review performed by our security team — this is not an automated capability of the Aikido tool itself. Aikido produces the raw findings; human expert review was applied to classify them against professional audit results.*

> ***Important**: The code analyzed by Aikido is the current open-source version of each Strike Finance repository. The TxPipe audits were performed on specific earlier commits (perpetuals: `2497f687`, forwards: `589b55f9` and later). Many findings in the TxPipe reports have status "Resolved," meaning the code was patched after the audit. Aikido is analyzing the post-fix code, so findings that were fixed will naturally not appear. This is noted in the classification as "Correctly Not Flagged — Code Fixed."*

Executive Summary

Metric	Forwards	Perpetuals	Combined
TxPipe Security Findings	11	13	24
Full Match (TP)	4	8	12
Partial Match	2	3	5
Correctly Not Flagged (code fixed)	2	2	4
False Negatives (no coverage)	3	0	3
Aikido Unique Findings	7	19	26

Scoring Models (unfixed code only)

Model	Forwards (9)	Perpetuals (11)	Combined (20)
Binary (full matches only)	44% (4/9)	73% (8/11)	60% (12/20)
Weighted (partial = 0.5)	56% (5/9)	86% (9.5/11)	73% (14.5/20)
Coverage (any match)	67% (6/9)	**100%** (11/11)	**85%** (17/20)

Key Takeaway: Aikido provides at least partial coverage on **85% of all professionally audited security findings** on unfixed code (100% on perpetuals). It also surfaces 26 additional findings that TxPipe did not flag. The only 3 undetected findings (STF-002, STF-006, STF-202) are pure business logic issues requiring multi-step protocol flow understanding — exactly where manual auditors add the most value.

Methodology

How Aikido Works

Aikido is a static analysis tool purpose-built for Aiken smart contracts. It operates on the typed AST produced by the Aiken compiler and employs:

- **75 pattern-based detectors** targeting Cardano-specific vulnerability classes
- **Cross-module signal propagation** via fixed-point function merging
- **Body signal analysis** tracking datum access, value comparisons, minting operations, and arithmetic patterns
- **Delegation-aware suppression** for withdraw-zero-pattern validators
- **Datum continuity tracking** to reduce false positives on state transition checks
- **Multi-lane architecture** (v0.3.0): compliance analysis, SMT verification, transaction simulation, CWC classification

What TxPipe Audits Cover

TxPipe performs professional security audits including:

- Manual line-by-line code review
- Business logic and protocol flow analysis
- Transaction diagram validation
- Custom exploit scenario construction
- Code quality and optimization recommendations

Classification Criteria

Classification	Definition	Binary Score	Weighted Score
Full Match (TP)	Aikido flags a finding that directly matches or subsumes a TxPipe finding	1.0	1.0
Partial Match	Aikido flags a related finding on the same validator/field — an auditor investigating the Aikido finding would discover the TxPipe issue	0.0	0.5
Correctly Not Flagged	TxPipe finding was resolved in current code — Aikido correctly doesn't flag it	—	—
False Negative (FN)	TxPipe identified a real issue with no Aikido coverage at all	0.0	0.0
Aikido Unique	Aikido flags an issue that TxPipe did not identify	—	—

Scoring models:

- **Binary**: Only full matches count. Conservative lower bound.
- **Weighted**: Partial matches count as 0.5. Reflects that Aikido pointed the auditor toward the right area.
- **Coverage**: Any match (full or partial) counts. Answers: "Would Aikido have flagged something in the vicinity of every TxPipe finding?"

Strike Forwards Comparison

TxPipe Audit: 12 November 2024, 17 total findings **Audited commit**: `589b55f9a53c363ad4e636e037cc31e354700e86` (and later commits) **Audited files**: `lib/constants.ak`, `lib/types.ak`, `lib/utils.ak`, `validators/collateral.ak`, `validators/agreement.ak`, `validators/always_fail.ak`, `validators/forwards.ak`

Findings Breakdown

TxPipe found 17 issues: 7 Critical, 1 Major, 3 Minor, 5 Info, 1 Style section (counted as 1).

Security-relevant findings: STF-001 through STF-007 (Critical), STF-101 (Major), STF-201 (Minor), STF-202 (Minor), STF-203 (Minor) = **11 security findings**

Code quality / informational: STF-301 (Info), STF-302 through STF-305 (Info), Style Recommendations = **6 non-security findings**

Detailed Comparison Table

TxPipe ID	Title	Severity	Status	Aikido Match	Classification	Aikido Detec
STF-001	UTxO address not validated in Create Forward	Critical	Resolved	Partial	TP (partial)	`missing-datum-in` `script-output` fla output without datum verificatio `forwards.mint`, w is the same mint handler where th address check w missing
STF-002	Potential loss of collateral if neither party deposits	Critical	Resolved	No	FN	Business logic: requires understanding th both `*_has_deposited_` `= False` creates permanently loc UTxO. Static ana cannot model 2-party deposit lifecycle
STF-003	Double satisfaction in operations requiring token burning	Critical	Resolved	Yes	TP	`quantity-of-doub` `counting` on `collateral.spend` detects that mul similar operation the same TX cou share burn coun
STF-004	Missing validations in	Critical	Resolved	Yes	TP	`missing-datum-in` `script-output` an `quantity-of-doub`

	Accept Forward operation					`counting` on `forwards.mint` an `collateral.spenc` flags the missin token count and datum checks
STF-005	Double counting of tokens in values	Critical	Resolved	Yes	TP	`quantity-of-doub` `counting` on `collateral.spenc` calls) and `forwards.mint/sp` — directly detec the `quantity_of-` based double counting vulnera
STF-006	One Side Deposit can be performed multiple times	Critical	Resolved	No	FN	Requires redeen action + state machine analysi the boolean fiel `CollateralDatum` not checked aga the input datum before update
STF-007	Missing datum fields validation in Create Forward	Critical	Resolved	Yes	TP	`incomplete-value` `extraction` and `unsafe-datum-deconstruction` o `forwards` — dete that datum field from the output not validated du creation
STF-101	Users could deposit assets after exercise date	Major	Resolved	No	Correctly Not Flagged	The code was fi to compare agai `get_upper_bound.` Aikido's `missing-` `validity-range` detector now validates the cu code correctly
STF-201	Prevent inclusion of reference scripts	Minor	Resolved	N/A	Correctly Not Flagged	Code was fixed audit. Reference script injection prevention adde
STF-202	One Side Deposit can be bypassed	Minor	Resolved	No	FN	Business logic: requires

						understanding t `BothSidesDeposit` be called withou prior `OneSideDepo` bypassing the intended two-st flow
STF-203	Party identity can be forged	Minor	Resolved	Partial	TP (partial)	`unsafe-datum-deconstruction` detects unsafe pattern matchin deposit operatic which is related the party identit forgery vector
STF-301	Do Datum comparisons in Data	Info	Resolved	Yes	TP	`unsafe-datum-deconstruction` — directly related t costly type-cast pattern for datu comparison
STF-302	Clean up output lookup in Both Sides Deposit	Info	Resolved	N/A	N/A	Code quality — security-relevan
STF-303	Standardize the output lookups	Info	Resolved	N/A	N/A	Code quality — security-relevan
STF-304	Cleanup output lookup in Accept Forwards	Info	Resolved	N/A	N/A	Code quality — security-relevan
STF-305	Various recommendations for the Types module	Info	Resolved	N/A	N/A	Code quality — security-relevan
Style	Style Recommendations (20.a-20.e)	Info	Resolved	N/A	N/A	Code style — no security-relevan

Forwards Summary

Category	Count
Full match (TP)	4 of 11
Partial match	2 (STF-001, STF-203)
Correctly not flagged (code fixed)	2

False negatives	3 (STF-002, STF-006, STF-202)
Binary catch rate (unfixed code)	**44%** (4/9)
Weighted catch rate (unfixed code)	**56%** (5/9)
Coverage (unfixed code)	**67%** (6/9)

Aikido Unique Findings on Forwards

Aikido flagged **13 findings** on forwards. Beyond those matching TxPipe findings, these are unique:

Detector	Severity	Module	Description
`unsafe-datum-deconstruction`	High	`collateral`	Unsafe Option datum deconstruction patterns
`missing-min-ada-check`	Info	`collateral`, `forwards`	Outputs produced without minimum ADA verification
`dead-code-path`	Info	`utils`	Unreachable function `get_address_hash_based_on_party`
`unused-import`	Info	`always_fail`	No function calls in validator

Strike Perpetuals Comparison

TxPipe Audit: Undated (commit `2497f6870c55c72a63d0550105afa251538d7eb8`) **Total findings**: 13 (10 High, 2 Medium, 1 unclassified — all effectively High severity) **Audited files**: `validators/orders.ak` , `validators/manage_positions.ak` , `validators/position_mint.ak` , `validators/pool.ak` , `validators/liquidity_mint.ak` , `lib/math.ak` , `lib/orders_validations.ak`

Detailed Comparison Table

TxPipe ID	Title	Severity	Aikido Match	Classification	Aikido Detector
ID-1	Use of Lower Bound for Current Time	High	Yes	**TP**	`missing-validity-range` on `orders.spend` and `position_mint.mint` — flags lower bound time manipulation risk, exactly matching this finding
ID-2	Missing Validation and Unbounded Fields in Position Datum	High	Yes	**TP**	`missing-datum-field-validation` on `pool` and `settings` — detects unbounded/unvalidated datum fields. Also `unsafe-redeemer-arithmetic` on `position_mint.mint` for

					the redeemer-sourced values
ID-3	Lack of Supply Check / Division by Zero	High	Yes	**TP**	`division-by-zero-risk` on `orders.spend` and `position_mint.mint` — directly detects the division that may fail when pool supply is zero
ID-4	Unsafe Asset Comparison Allows Over-Lending	High	N/A	Correctly Not Flagged	Code was fixed post-audit to use `==` instead of `match(>=)`. Aikido correctly doesn't flag the fixed version
ID-5	Misuse of match for Multi-Asset Value Comparison	High	N/A	Correctly Not Flagged	Code was fixed post-audit. The `match(>=)` pattern was replaced
ID-6	Missing Update to total_lended_amount in Pool Datum	High	Partial	**Partial Match**	Aikido's `missing-datum-field-validation` on `pool` explicitly names `total_lended_amount` as an unvalidated field. While Aikido doesn't detect the *missing update* specifically, it flags the exact field as lacking validation — an auditor investigating would discover the update omission
ID-7	Missing Validation for position_asset_amount	High	Yes	**TP**	`missing-datum-field-validation` and `unsafe-redeemer-arithmetic` on `position_mint.mint` — detects that user-submitted datum fields are used without validation
ID-8	Missing Validation of current_usd_price in Close Position	High	Yes	**TP**	`unsafe-redeemer-arithmetic` on `orders.spend` — flags redeemer-tainted arithmetic where `current_usd_price` from the redeemer flows into calculations

					without bounds checking
ID-9	Missing Validation of Lent Amount Returned to Pool	High	Yes	**TP**	`fee-calculation-unchecked` on `manage_positions.spend` — detects that the repayment calculation lacks validation against the expected return amount
ID-10	Incorrect Liquidation Condition Due to Improper Loss Calc	High	Yes	**TP**	`integer-underflow-risk` on `manage_positions.spend` — flags the subtraction that can underflow when `total_value_loss` is negative, causing the liquidation logic to behave incorrectly
ID-11	Token Dust Attack on Pool Output	Medium	Partial	**Partial Match**	Aikido's `incomplete-value-extraction` warns "doesn't validate the full Value — other native assets may be drained," which is the exact attack vector of token dust injection. The specific `match(>=)` mechanism differs but the vulnerability class is correctly identified
ID-12	Missing Token Burn in liquidate_position Flow	Medium	Partial	**Partial Match**	Aikido's `state-machine-violation` on `manage_positions` flags "Terminal action 'Close' doesn't access mint field (may need token burn)" — correctly identifying that termination paths lack burn verification. The specific path (liquidate vs close) differs but the burn-omission pattern is detected

ID-13	Missing Token Validation in Output Value	Medium	Yes	**TP**	`quantity-of-double-counting` on `manage_positions.spend` — detects that output token composition is not fully validated, allowing unauthorized tokens to slip through

Perpetuals Summary

Category	Count
Full match (TP)	8 of 13
Partial match	3 (ID-6, ID-11, ID-12)
Correctly not flagged (code fixed)	2
False negatives	0
Binary catch rate (unfixed code)	**73%** (8/11)
Weighted catch rate (unfixed code)	**86%** (9.5/11)
Coverage (unfixed code)	**100%** (11/11)

Aikido Unique Findings on Perpetuals

Aikido flagged **34 findings** on perpetuals. Beyond those matching TxPipe findings, these unique findings were not identified by TxPipe:

Detector	Severity	Module	Description
`missing-minting-policy-check`	Critical	`liquidity_mint`	Minting policy never accesses the transaction's mint field — arbitrary tokens can be minted under this policy
`unrestricted-minting`	Critical	`liquidity_mint`	Complementary finding: the minting policy has no restrictions on what can be minted
`withdraw-zero-trick`	High	`liquidity_mint`, `pool`	The withdraw-zero trick allows bypassing staking credential checks
`invariant-violation`	High	`manage_positions`	Value conservation not verified across the position management flow
`insufficient-staking-control`	Medium	`manage_positions`	Outputs don't constrain staking credential, allowing delegation hijacking
`cheap-spam-vulnerability`	Medium	`manage_positions`	Low-cost transaction spam possible against the validator

`rounding-error-risk`	Medium	`orders`, `position_mint`	Integer rounding in financial calculations could be exploited
`state-machine-violation`	Medium	`manage_positions`	Close action may not properly enforce state machine transition rules
`missing-min-ada-check`	Info	Multiple	Outputs without minimum ADA verification
`dead-code-path`	Info	`utils`, `math`	Unreachable functions detected
`excessive-validator-params`	Info	`position_mint`	6 parameters (recommended max: 4)

Systematic Gap Analysis

What Aikido Catches Well

Category	Detection Rate	Examples
Missing datum field validation	High	ID-2, ID-7, STF-004, STF-007
Arithmetic vulnerabilities (division by zero, underflow)	High	ID-3, ID-10, STF-005
Token counting / double satisfaction	High	STF-003, STF-005, ID-13
Time manipulation via validity range	High	ID-1
Redeemer-tainted arithmetic	High	ID-8, ID-9
Unsafe value comparison patterns	High	Related to ID-4, ID-5

What Static Analysis Misses Entirely (3 findings)

All 3 completely undetected findings share a common root cause: **multi-step business logic**.

Category	Reason	Finding
2-party deposit lifecycle	Requires modeling that *both* parties failing to deposit creates a permanently locked UTxO	STF-002
Deposit replay attack	Requires understanding that `OneSideDeposit` doesn't check input datum booleans before update	STF-006
Two-step flow bypass	Requires understanding that `BothSidesDeposit` can be called without prior `OneSideDeposit`	STF-202

What Static Analysis Partially Catches (5 findings)

These findings weren't precisely identified but Aikido flagged a closely related issue on the same validator/field:

Finding	Partial Detection	What's Missing
STF-001 (address not validated)	`missing-datum-in-script-output` on same mint handler	Address-level validation vs datum-level
STF-203 (party identity forgery)	`unsafe-datum-deconstruction` on deposit ops	Exact forgery vector vs general unsafe pattern
ID-6 (missing datum field update)	`missing-datum-field-validation` names `total_lended_amount` directly	Detects unvalidated field, not missing *update*
ID-11 (token dust attack)	`incomplete-value-extraction` warns "other native assets may be drained"	Correct vulnerability class, different mechanism
ID-12 (missing burn in liquidation)	`state-machine-violation` flags "terminal action lacks mint access"	Correct pattern, different code path

Gap Significance

The 3 completely missed findings all require **protocol-level semantic understanding** of multi-step transaction flows — exactly where professional manual auditing adds the most value. Aikido and manual audits are **complementary rather than competing** approaches: Aikido handles the 85% of findings catchable through static patterns, freeing auditors to focus on complex business logic.

Options & Staking Results (No TxPipe Baseline)

No professional audit exists for these two Strike Finance contracts. Aikido findings are presented as standalone results.

Options Smart Contracts (10 findings)

Detector	Severity	Confidence	Module	Description
`missing-validity-range`	High	Definite	`options`	Lower bound time manipulation risk
`unsafe-match-comparison`	High	Likely	`options`	Unsafe `match(..., >=)` value comparison (spend)
`unsafe-match-comparison`	High	Likely	`options`	Unsafe `match(..., >=)` value comparison (mint)
`unsafe-redeemer-arithmetic`	High	Likely	`options`	Redeemer-tainted arithmetic
`multi-asset-comparison-bypass`	High	Likely	`options`	Multi-asset comparison bypass possible (spend)
`multi-asset-comparison-bypass`	High	Likely	`options`	Multi-asset comparison bypass possible (mint)
`unbounded-datum-size`	Medium	Possible	`types`	Datum field `issuer_bech32_address` has unbounded type

`value-comparison-semantics`	Medium	Possible	`options`	Inequality match comparator on Value may miss assets
`dead-code-path`	Info	Possible	`utils`	Unreachable function `get_address_outputs`
`excessive-validator-params`	Info	Possible	`options`	5 parameters (max recommended: 4)

Notable: Options contracts show the same `unsafe-match-comparison` vulnerability pattern (ID-4/ID-5 equivalent) that TxPipe flagged in perpetuals and was fixed there. This suggests options may have similar over-lending/value bypass risks that haven't been addressed yet.

Staking Smart Contracts (6 findings)

Detector	Severity	Confidence	Module	Description
`tautological-comparison`	Critical	Definite	`staking`	Tautological comparison: `datum.mint_policy_id == datum.mint_policy_id` — always true, meaning the intended check is completely bypassed
`quantity-of-double-counting`	High	Possible	`staking`	Multiple `quantity_of` calls may allow double-counting (spend)
`quantity-of-double-counting`	High	Possible	`staking`	Multiple `quantity_of` calls may allow double-counting (mint)
`missing-validity-range`	Medium	Definite	`staking`	Time-sensitive datum but no validity range check
`incomplete-value-extraction`	Medium	Possible	`staking`	Incomplete Value check via `quantity_of`
`withdraw-amount-check`	Medium	Possible	`staking`	Withdrawal existence-only check — amount not verified

Notable: The tautological comparison (`datum.mint_policy_id == datum.mint_policy_id`) is a definite-confidence Critical finding — this is a likely copy-paste bug where the developer compared a field to itself instead of to an expected value.

Metrics Summary

By-Finding Classification

Classification	Forwards	Perpetuals	Total
Full Match (TP)	4	8	12
Partial Match	2	3	5

Correctly Not Flagged (code fixed)	2	2	4
False Negative (no coverage)	3	0	3
Not Applicable (info/style)	6	0	6
Total security findings	**11**	**13**	**24**
Unfixed security findings	**9**	**11**	**20**

Three Scoring Models

We evaluate Aikido's performance against unfixed security findings using three complementary models:

Model	Description	Forwards	Perpetuals	**Combined**
Binary	Only full matches count (conservative lower bound)	44% (4/9)	73% (8/11)	**60%** (12/20)
Weighted	Full match = 1.0, Partial = 0.5	56% (5/9)	86% (9.5/11)	**73%** (14.5/20)
Coverage	Any match (full or partial) counts — "would an auditor using Aikido have been pointed toward this issue?"	67% (6/9)	**100%** (11/11)	**85%** (17/20)

Interpretation: The Coverage metric answers the most practical question — "If I used Aikido before a manual audit, would every TxPipe finding have been at least partially flagged?" On perpetuals, the answer is **yes, 100%**. On forwards, 3 findings (STF-002, STF-006, STF-202) have zero Aikido coverage — all three are pure business logic issues requiring multi-step protocol flow understanding.

Recall by Severity (Coverage Model)

TxPipe Severity	Total	Full Match	Partial	Coverage Rate
Critical	7	5	0	**71%**
High	10	7	1	**80%**
Major	1	—	—	Code was fixed
Medium	3	1	2	**100%**
Minor	3	0	1	**33%**
Info	5	1	0	20%

Observation: Aikido achieves 100% coverage on Medium-severity findings and 80% on High. The 3 uncovered findings are all in the Critical/Minor categories and involve business logic that static analysis fundamentally cannot model.

Aikido Unique Findings

Metric	Value

Aikido findings matching TxPipe	17 (12 full + 5 partial)
Aikido-only findings (not in TxPipe)	26
Unique finding rate	**60%** of all Aikido findings are additive

These 26 unique findings include 2 Critical (`missing-minting-policy-check` , `unrestricted-minting`), 4 High, and 12 Medium-severity issues that TxPipe did not flag — demonstrating that Aikido provides additive security value even alongside professional audits.

Conclusion

Aikido as a Pre-Audit Tool

1. **85% coverage on unfixed security findings**: Aikido provides at least partial coverage on 17 of 20 unfixed findings from professional TxPipe audits. On perpetuals specifically, coverage is **100%** — every single TxPipe finding was flagged in some form.
2. **60-73% precision**: Using binary scoring (conservative), Aikido directly matches 60% of findings. Using weighted scoring (partial = 0.5), this rises to 73%.
3. **Complementary coverage**: Aikido surfaces 26 additional findings that TxPipe did not flag, including critical minting policy issues and the withdraw-zero trick — demonstrating additive value even alongside professional audits.
4. **Highest accuracy where it matters most**: 80% coverage on High-severity findings and 100% on Medium — Aikido is most reliable at detecting the vulnerability classes with highest exploitability.
5. **Minimal, well-defined blind spots**: Only 3 of 20 unfixed findings have zero Aikido coverage. All 3 are pure business logic issues requiring multi-step protocol flow understanding — exactly where professional auditors add the most value.
6. **Zero-cost scaling**: Unlike manual audits (typically $30,000-$100,000+ per engagement), Aikido runs in seconds and can be integrated into CI/CD for continuous monitoring.

Recommended Usage

- **Pre-audit**: Run Aikido before engaging a professional auditor to fix easy wins, reducing audit scope and cost
- **During development**: Integrate into CI/CD to catch vulnerabilities as code is written
- **Post-audit**: Monitor for regressions after patches are applied
- **Unaudited contracts**: For the many Aiken projects that cannot afford professional audits, Aikido provides 85% coverage at zero cost

Market Position

Aikido is the **only static analysis tool** purpose-built for Aiken smart contracts. With ~200 active Aiken developers, $423M in Cardano DeFi TVL, and zero direct competition, Aikido fills a critical gap in the Cardano security ecosystem.
